VR (Virtual Reality) and AR (Augmented Reality) virtual image detection machines are professional instruments used to detect the virtual image characteristics of these two types of devices. VR devices aim to create a completely virtual environment for users, and the detection machine mainly focuses on measuring the imaging quality of virtual images. It simulates the way human eyes observe, captures virtual images projected by devices through optical sensors, analyzes parameters such as distance, size, clarity, distortion of virtual images, and determines whether VR devices can provide users with a realistic and comfortable immersive experience. AR is the process of overlaying virtual information onto the real world. In addition to focusing on the quality of the virtual image itself, the detection machine also needs to consider the degree of fusion between the virtual image and the real scene. It will combine the real scene captured by the camera to detect the position accuracy, color consistency, transparency and other parameters of the virtual image, ensuring that virtual elements can naturally integrate into the real environment.
