Xenon-133 is a radioactive isotope of xenon, a noble gas found in trace amounts in the Earth's atmosphere. It is produced as a fission product during nuclear reactions, particularly in nuclear reactors and nuclear weapons detonations. Xenon-133 has a half-life of about 5.25 days, which means that it decays relatively quickly compared to some other radioactive isotopes.

One of the notable uses of xenon-133 is in medical imaging, particularly in lung ventilation studies. Since xenon-133 is inert, it can be inhaled by patients without causing harm. Its radioactive decay emits gamma radiation, which can be detected by specialized imaging equipment, allowing for the visualization of air flow within the lungs. This technique is particularly useful in diagnosing pulmonary conditions and assessing lung function.

Xenon-133 has also been used in atmospheric studies to trace air movements and in studies related to environmental pollution. Additionally, it has applications in research and industry, particularly in areas where a radioactive tracer is needed. However, its short half-life limits its utility in some long-term studies.

The global Xenon-133 Gas market size is projected to grow from US\$ million in 2024 to US\$ million in 2030; it is expected to grow at a CAGR of %from 2024 to 2030.
