## **Abstracts**

Night vision devices collect ambient light, which includes moonlight, starlight or infrared (IR) light through the front lens of the device. This light is made of photons. It is converted to electrons by passing it through a photocathode tube. The electrons are then amplified through a chemical and electrical process. After that, the resulting light is thrown against a phosphorous screen that converts the electrons back to the visible light, which the user sees through the eyepiece. The image is a clear, green-hued, amplified recreation of the scene.

This report elaborates the market size, market characteristics, and market growth of the Night-Vision Goggles industry, and breaks down according to the type, application, and consumption area of Night-Vision Goggles. The report also conducted a PESTEL analysis of the industry to study the main influencing factors and entry barriers of the industry.
