Abstracts

Galvanic cells operate on DC (direct current), which is when electrons flow in one direction. This is how redox reactions work. Electrons go from one end to the other.

In AC (alternating current), energy is transferred through the back and forth movement of electrons. This is not appropriate for redox reactions, as the electron current should move in one direction, rather than alternate (moving back and forth).

Since electrolysis works by inputting energy to force a redox reaction to occur, it must push electrons in a particular direction, which can only be achieved with a DC power source.
