Abstracts

Gene therapy is an experimental medical treatment that uses specific types of genes to treat or prevent several types of diseases. Gene therapy is also used to treat several hereditary diseases, wherein the mutated defective gene is replaced with the functional gene. Gene therapy is being widely studied by researchers all over the world for the treatment of several diseases such as immune deficiencies, hemophilia, Parkinson's disease, cancer, and even HIV, through different approaches. Three primary approaches that are being studied and practiced in the gene therapy are replacement of the mutated disease-causing gene with the healthy gene, inactivation of the mutated gene, and introduction of the new gene to fight against the disease. In the gene therapy treatment, a functional gene is inserted into the genome of an individual's cells and tissues by using a carrier known as 'vector'. Viruses is the most common type of vectors used in gene therapy, which is genetically altered to carry the normal human DNA. Over the last few years, gene therapy has emerged as a promising treatment option for several diseases including inherited disorders and certain types of cancers and viral infections.

The Gene Therapy market revenue was xx Million USD in 2016, grew to xx Million USD in 2020, and will reach xx Million USD in 2026, with a CAGR of xx during 2020-2026.
