## **Abstracts**

Imaging photometers refer to instruments that measure the luminous intensity of a light source, by comparing it with the standard source. This comparison could be done with a photoelectric cell (Pritchard photometer), or with the human eye (SEI exposure photometers or Lummer Brodhun). In flicker photometer, the visual photometer observer sees a field illuminated alternately with two sources which are to be compared. Once the flicker sensation disappears, the intensity of the test source could be concluded by reading the reference standard source with which it is compared. To determine the difference, frequency of alteration at a point which is below critical fusion frequency, but for the determination of distinction in the color or color difference, the frequency of alteration is chosen at a point which is above the critical fusion frequency. In other words, imaging photometers refer to instruments which find application in measurement of light intensity and understanding optical properties of surface and solutions. The imaging photometer finds application in detection of photomultipliers or photodiodes and photo resistors. The photometer measures light following the passage of light through monochromatic or filter fir the determination at defined wavelengths for analyzing the spectral distribution of light. Imaging photometers find application in photography to determine the correct exposure for the photograph. Modern cameras with latest technology have built in imaging photometers. Advanced imaging photometers with latest technology are capable of measuring light intensity at different positions of the image or picture. Further, the imaging photometers use a wide range of algorithms for the determination of the most appropriate exposure in the final picture. Traditionally, a photometer used to be separate from the body of the camera.

The Imaging Photometers market revenue was xx Million USD in 2016, grew to xx
