Abstracts

In biochemistry, kinases are a class of enzymes that transfer phosphate groups from high-energy donor molecules to specific target molecules. The largest group of kinases is protein kinases. Kinase inhibitor is an enzyme inhibitor that can block the action of kinase. Kinases add a phosphate group to a specific target molecule in a process called phosphorylation, which can affect its activity and functional level. Protein kinase inhibitors can be subdivided according to the amino acids (such as serine, threonine, or tyrosine) on the phosphate-added protein to inhibit the phosphorylation of the amino acid. Phosphorylation is often a necessary step for the growth of certain cancers and inflammatory diseases, which means that inhibiting the enzyme that triggers phosphorylation provides a way to treat these diseases.
