Abstracts

Microneedles are tiny needles, small enough that they are measured in millionths of a meter, designed to deliver medicines. Typically grouped together in a large number, microneedles are designed to be applied to the skin like a patch. When pressed onto the skin surface, the needles are able to cross the very outermost layer of the skin, which then creates microscopic pores, allowing the medicine to enter the body. Because the needles are very small, the dermal nerves and blood vessels are not affected, so there is no pain or bleeding when the patch is applied. The needles are hard when they are dry, so they can be easily applied to the skin. The medicine is held in a reservoir adjacent to the microneedles. When inserted, the microneedles draw in the fluid that bathes cells, and they then begin to swell. This opens up the structure of the material. When the fluid from the skin enters the patch, it dissolves the reservoir that holds the medicine, which is then able to move through the microneedles into the dermal layers of the skin that is rich in blood vessels. These blood vessels then transport the medicine to the rest of the body.
