Abstracts

An optical coating is composed of a combination of thin film layers that create interference effects used to enhance transmission or reflection properties within an optical system. The performance of an optical coating is dependent upon the number of layers, the thickness of the individual layers, and the refractive index difference at the layer interfaces. Many common types of coatings are used on precision optics, including Anti-Reflection (AR) Coatings, High Reflective (Mirror) Coatings, Beamsplitter coatings, and Filter coatings such as shortpass, longpass, and notch filters. Anti-reflection coatings are included on most refractive optics and are used to maximize throughput and reduce unwanted reflections. High Reflective coatings are designed to maximize reflectance at either a single wavelength or across a broad range of wavelengths and are most often used to create mirrors. Beamsplitter coatings are used to divide incident light into known transmitted and reflected light outputs.
