Abstracts

Shock, syncope, and sudden death are manifestations of acute circulatory failure. Shock occurs primarily due to reduced blood volume (also called hypovolemia). The treatment of shock requires the blood volume to be restored as early as possible. There are different types of fluids used in the management of shock including whole blood plasma, plasma substitute or plasma expander, colloidal solution of dextran, colloidal solution of hydroxyethyl starch, and crystalline solution of sodium chloride and starch. Plasma expanders are agents that have high molecular weight and that boost the plasma volume by increasing the osmotic pressure. After administration, plasma expanders remain for an enough time to restore the volume of the circulatory fluid by increasing the osmotic pressure. There are two types of plasma expanders: colloidal and crystalloid. Crystalloid fluid is commonly used to expand the plasma volume. Crystalloid fluid is balanced salt solution that freely crosses the capillary walls and stays in the intravascular space for a shorter time compared to colloidal fluid. Also, the crystalloid fluids exhibit an early plasma expansion, which is of shorter life span. Crystalloid fluid is evenly distributed into the intracellular space. Moreover, it absorbs extracellular water into the intravascular space by creating osmotic pressure. However, absorption of excessive water by crystalloid fluid can cause pulmonary and peripheral edema.
