## Abstracts

Recombinant or purified protein vaccines consist of protein antigens that have either been produced in a heterologous expression system (e.g., bacteria or yeast) or purified from large amounts of the pathogenic organism. The vaccinated person produces antibodies to the protein antigen, thus protecting him/her from disease.

Recombinant/purified protein vaccines are based on the concept that humoral immune responses mounted to an infection are often targeted toward specific localized regions on the surface of protein antigens known as epitopes. The recombinant proteins for vaccination are produced by expressing these immunogenic proteins using heterologous expression systems. The immunogenic protein antigens can also be purified from the infectious organism. Once purified, protein antigens, recombinant and endogenous, are administered with an adjuvant to boost the immune response. Administering just the most immunogenic protein or proteins from an infectious organisms as a vaccine produces a more targeted immune response. This strategy also eliminates the risk of active infection that can occur with live attenuated vaccines or even inactivated vaccines where inactivation is incomplete.
