Abstracts

Latent TB occurs when a person has the TB bacteria within their body, but the bacteria are present in very small numbers. They are kept under control by the body's immune system and do not cause any symptoms.

People with latent TB do not feel sick and are not infectious. They cannot pass the bacteria on to other people. In addition they will usually have a normal chest x-ray and a negative sputum test. It is often only known that someone has latent TB because they have had a test, such as the TB skin test.

The treatment of latent TB is considered by many people to be an important part of TB prevention.

It is not recommended that everyone with latent TB infection (LTBI) should have TB treatment. Rather it is recommended that certain "target" groups should receive treatment. The main "target" groups considered by the World Health Organisation (WHO) to be most at risk from progressing from latent to active TB include people in low TB burden countries:

- who have had recent contact with an infectious patient;
- with silicosis;
- infected with both TB and HIV;
- who have been or who are in prison;
- who are immigrants to a low burden country from a high burden country;

who are homeless;
who are an illicit drug user;
who have certain clinical conditions, or conditions which compromise their immune system, such as people with diabetes, and people with chronic renal failure.
In high TB burden countries the populations that are most strongly recommended for the treatment of latent TB infection are people living with HIV, and children under five who are household contacts of pulmonary TB cases.

The Tuberculosis Drugs market revenue was xx Million USD in 2016, grew to xx Million USD in 2020, and will reach xx Million USD in 2026, with a CAGR of xx during 2020-2026.
