## Abstracts

Wind turbine generators use induction and permanent- magnet designs. There are many variations of these two, but in general terms, the induction generator must be spun at about 1,000 rpm or more to produce useful power. It produces current by first generating an electric field by passing alternating current (ac) through a coil. A series of these coils are mounted on a rotating structure (a rotor) that is turned by the wind through the drive train. Surrounding the rotor is a stationary series of coils, a stator. When the electric fields on the rotor pass coils on the stator, the field induces a current in the stator coils which is conducted away as output. Induction generators are not self-exciting. That means they require an external power supply to produce a magnetic flux or field.

Based on the Wind Turbine Generator market development status, competitive landscape and development model in different regions of the world, this report is dedicated to providing niche markets, potential risks and comprehensive competitive strategy analysis in different fields. From the competitive advantages of different types of products and services, the development opportunities and consumption characteristics and structure analysis of the downstream application fields are all analyzed in detail. To Boost Growth during the epidemic era, this report analyzes in detail for the potential risks and opportunities which can be focused on.
