Animal / Veterinary ultrasound is based on the different densities and different ultrasound propagation velocities of different tissues and organs in animals, that is, the characteristics of different acoustic impedances, which cause it to generate a certain frequency of ultrasound. This ultrasound is injected into the animal, The interface of the device generates reflected echoes; the reflected echoes of different sizes, which in turn process the received echoes, detection, and digital scanning conversion to form a standard video signal, and display a cross-sectional image of the organ on the monitor screen . A high-tech method for carrying out cross-section observation of a living body without any damage and stimulation has become a useful assistant for veterinary diagnostic activities and a monitoring instrument necessary for scientific research such as live egg collection and embryo transfer.
