Abstracts

Caries detection device aims to overcome the limits of traditional diagnostic methods and can help to identify caries at an earlier stage. Conventionally, dental caries has been diagnosed visually and by using explorers and radiographs. Mostly, caries detection devices are used to evaluate a visually suspicious area on a tooth. They can be used to monitor the progression of caries and help in the decision to prevent, remineralize, or restore. They can be used to examine the enamel structure preceding to sealant placement, and some caries detection devices can also be used to check the sealant margins over time. Additionally, some quantifiable caries detection devices can be used on patients longitudinally and any changes can be recorded, addressing treatment as needed. The device allows clinicians to deliver customized patient care. Recent caries management has progressed from a surgical approach to a non-invasive, preventive and disease management techniques. There are a number of modalities for recognizing caries. The most widespread device used to detect caries through the use of fluorescence. It detects bacteria on the surface of the tooth by illuminating it with violet light. It represents a major improvement over more primitive methods such as bitewing digital radiography and visual identification of caries.
