Abstracts

During cerebral malaria there is a state of unarousable coma with malaria infected blood in the peripheral circulation. The condition of coma is due to some other type of infections or hypoglycemia. The presence of retinopathy has been an addition in the clinical diagnosis of both adult and children. The postmortem studies done for observing the pathophysiology of cerebral malaria has found that Plasmodium falciparum infections accounts for majority of the cerebral malaria cases showing a common feature of vascular sequestration in the brain of infected erythrocytes. There is a difference between cerebral malaria in adults and in children. They can be differentiated based on the infected erythrocytes sequestration pattern with variable vascular pathology.
