Abstracts

In CLIP, liquid photopolymer resin is selectively exposed to a UV light source and is solidified into parts. Despite initial appearances, CLIP is unique from SLA and DLP as it is a truly continuous process that “grows” parts, removing the discrete steps of previous printing methods. CLIP’s innovation lies in its oxygen-permeable membrane that creates a dead zone underneath the part (known as a persistent liquid interface), allowing for continuous curing as the part is drawn out of the resin. Instead of using a layer-by-layer approach, CLIP uses a digital projector and various microcontrollers to project an ever-changing picture of a 3D model, streamlining the print into a layer-less design.
