Diabetes is one of the growing concerns among adults 18 years of age and above. World health Organization (WHO) estimates that the global prevalence of diabetes is increased to 8.5% in 2014 as compared to 4.7% in 1980. Diabetes is identified as one of the major cause of lower extremity (LE) or peripheral edema, venous insufficiency and deep vein thrombosis, leading to multiple or combined etiologies. Compression therapy is a non-invasive treatment regime to improve the blood circulation in patients suffering from diabetes, varicose veins, and spider veins thus maintaining desired pressure in the feet's and legs. Compression socks accelerate venous blood flow by providing a gently graduated support to leg veins and valves creating improved blood flow. Compression socks are available in varying degrees of compression ranging from mild to higher levels of compression. The levels of compression are expressed in millimeters of mercury (mmHg), and different levels of compression socks are used in a treatment of different medical conditions. A mild level compression therapy (up to 25mmHg) is used to relieve the symptoms of swelled and paining legs, varicose and spider vein. High levels of compression therapy, greater than 25mmHg is considered contradiction for a diabetic patient. The low-level compression therapy socks do not require a physician's prescription while higher therapeutic compression socks are not sold without the doctor's prescription. Compression socks are available in various fits and sizes are often considered as the first line of treatment for varicose veins, spider veins, and edema in patients with diabetes. Apart from this compression therapy is largely exploited by athletes with venous insufficiency. The compression socks market is expected to generate substantial revenues over the forecast period.
