Differential Scanning Calorimetry (DSC) is the most regularly used technique for thermal analysis. It works by measuring the enthalpy changes in various samples because of the changes in their physical and chemical properties as a function of temperature or time. It measures heat of the sample relative to a reference at the time of physical transformation such as phase transition. Digital Scanning Calorimetry is one of the widely accepted technique in analytical chemistry. With this technique, it becomes possible to detect fusion, crystallization events, glass transition temperatures and study about oxidation as well as other chemical reactions. With this technique, one can learn a lot more than just a polymer's heat capacity. Researchers and scientists are able to gather critical data before, during and after creation of different products for industries including the pharmaceutical industry, food science and more.
