Abstracts

“Dry” (plasma) etching is used for circuit-defining steps, while “wet” etching (using chemical baths) is used mainly to clean wafers. Dry etching is one of the most frequently used processes in semiconductor manufacturing. Before etching begins, a wafer is coated with photoresist or a hard mask (usually oxide or nitride) and exposed to a circuit pattern during photolithography. Etching removes material only from the pattern traces. This sequence of patterning and etching is repeated multiple times during the chip making process.
