Abstracts

Epidermal growth factor receptor (EGFR) is a type of protein, which is located on the surface of human body cells. Any mutation in EGFR gene can lead to various types of cancer. EGFR functions as a biomarker for non-small cell lung cancer (NSCLC) and due to the mutation of EGFR gene a person may suffer from cancer or may have a tumor growth. Tumors with genetically altered EGFR gene are referred to as EGFR-mutated tumors. EGFR mutation is generally observed in NSCLCs, especially in adenocarcinoma tumors. According to the International Association for the Study of Lung Cancer, American Thoracic Society and European Respiratory Society, there are around 50% of surgically resected lung adenocarcinomas in EGFR mutations. These mutations are related to micro papillary predominant subtype and the bronchioloalveolar carcinoma. EGFR biomarker is used in diagnosis of patients with NSCLC. Targeted therapy involving tyrosine kinase inhibitors such as gefitinib and erotinib is used in the treatment of patients with NSCLC. EGFR biomarker detects the presence of specific alterations in EGFR gene, which may lead to the development of tumor.
