Abstracts

Elastic strain sensors can realize the monitoring of human motion and physiological parameters and the force perception of robots, and have important application prospects in the fields of medical rehabilitation, sports fitness and robot skin. Generally, elastic strain sensors are used to detect the deformation of the human body or the robot during the movement process, and then perceive the movement state of the human body or the robot. In practical applications, in addition to detecting deformation, it is often necessary to know the magnitude of the force. For example, the elastic strain sensor acts as the skin of the robot, and then senses the weight of the robot's grasping load by detecting the magnitude of the force; the elastic strain sensor evaluates the rehabilitation effect of patients with joint injuries by detecting the force. Existing elastic strain sensors are generally composed of polymers and conductive materials, and their modulus is generally in the order of hundreds of kPa to MPa.
