## Abstracts

Electrical coils or electromagnetic coils are conductive metallic wires wound around a bobbin in order to create and electromagnetic flux force around the electrical coil winding. The coils that are wound are coated with an insulating material to prevent current leakage resulting in short circuiting the coil winding. Electrical wire wound around in a single direction makes up the simplest form of electrical coil windings while two or more coil windings around a common core are also sold in the market for specific operations and are known as inductively coupled electrical coil windings. Various metals are used to produce an electrical coil winding but copper is the most dominant metal type used for its construction due to high electrical conductivity, resistance to corrosion, tensile strength, ductility, low thermal expansion and durability. The core or the heart of an electric coil windings can be a simple plastic insulating material or a magnetic material depending upon the intensity of magnetic field required. These electrical coil windings are known as iron core coil windings while electrical coil windings without the magnetic core are called the air core coil windings. The simplicity of a design of an electric coil winding over the advantages offered by its dynamic functions as well as the increase in the manufacture of electrical and electronic devices is anticipated to aid the electrical coil windings market from the global perspective.
