Abstracts

Foil strain gauge is a sensor used to measure the relative change of material length (strain) due to the applied force. This deformation is recorded as compression or tension and is greatly affected by the elastic properties of the tested material. Positive strain refers to the elongation of mechanical parts, while negative strain refers to the compression of materials. Foil strain gauge is used to determine the value and direction of strain. This is achieved through a measurement grid, which is usually installed on the material surface to obtain the applied strain as the effect of resistance change on the nominal resistance and sensitivity factor of foil strain gauge. It records compression as a decrease in resistance and elongation as an increase.
