Abstracts

Helicobacter Pylori Resistance Testing is used for the reliable identification of Helicobacter pylori and its resistances to fluoroquinolones and clarithromycin.

In most of these illnesses, initial eradication treatment is successful. Since, however, this initial therapy fails in about 10% of treated patients.

Because of such failed treatments, the rate of resistance to first-line antibiotics increases. This rate is over 80% for clarithromycin in a patient who has already had several treatments. Consequently alternative antibiotics must be resorted to, for example, from the fluoroquinolone group. But even here, there are already initial resistances in the case of H. pylori. Thus, a biopsy to test resistances should be taken no later than after the first failed treatment, in order to find the best antibiotic combination for the patient.
