Abstracts

The implantable miniature telescope (IMT) is the first surgical intervention approved for patients with end-stage AMD. It was approved by the U.S. Food and Drug Administration in July 2010. This telescope implant is an intraocular visual prosthetic device, which is inserted into the lens capsule during cataract extraction. The power of this miniature telescope helps to magnify images two to three times their original size with the goal of improving the central vision in one eye of patients with moderate to profound visual impairment. The non-implanted eye continues to see with peripheral vision, while the eye with the telescope takes on detailed central vision. Patients with implanted miniature telescope also need therapy to help re-train their brain to use each eye differently.
