Abstracts

An encoder is a device that compiles and converts signals (such as bitstreams) or data into signals that can be communicated, transmitted, and stored. An encoder converts an angular or linear displacement into an electrical signal, the former called a codec, and the latter a yardstick. According to the readout mode, the encoder can be divided into contact type and non-contact type. According to the working principle, encoders can be divided into incremental and absolute types. The incremental encoder converts the displacement into a periodic electrical signal, and then converts the electrical signal into a counting pulse. Each position of the absolute encoder corresponds to a certain digital code, so its indication value is only related to the starting and ending positions of measurement, and has nothing to do with the middle process of measurement.
