Abstracts

A nondispersive infrared sensor (NDIR) typically consist of an IR source, a sample chamber, a light filter, and an IR detector. Typically, a second chamber containing a reference gas runs in parallel to the sampling chamber. IR light is directed through the atmospheric sampling chamber to the detector. The methane gas in the sampling chamber absorbs light at specific wavelengths. A filter in front of the detector blocks out light that is not at the desired wavelength, so the detector measures the attenuation at the specified wavelength only, which is used to determine the concentration of methane present.
