Centrifugal Chiller is a centrifugal compressor uses a rotating disk or impeller to force gas to the rim of the impeller, increasing the velocity of the gas; a diffuser converts the velocity energy to pressure energy, the chiller then uses the vapor compression cycle to chill water (or other fluids) and transfers the heat collected from the chilled water plus the heat from operating compressor to a second water loop that can be cooled by a Cooling Tower.

Magnetic-bearing centrifugal chillers use a permanent magnet synchronous compressor motor. Such a motor has a significant efficiency increase over an induction motor, especially at low motor speeds. Instead of physical bearings, magnetic levitation makes for a virtual frictionless operation. The motor also does not require oil lubrication; oil in the chiller evaporator creates a decrease in efficiency over time as the tubes foul, lessening heat transfer. In addition, the motor has an extremely low inrush current at start-up and the regenerative power system keeps bearings powered until the shaft stops spinning, which enables it to ride through short durations of power loss.
