Abstracts

In maskless photolithography system, the radiation that is used to expose a photosensitive emulsion (or photoresist) is not projected from, or transmitted through, a photomask. Instead, most commonly, the radiation is focused to a narrow beam which directly writes the image into the photoresist, one or more pixels at a time. A key advantage of maskless photolithography is the ability to change lithography patterns from one run to the next, without incurring the cost of generating a new photomask. This may prove useful for double patterning.
