Abstracts

Nichrome alloy is also known as nickel-chrome, nickel-chromium alloy, chromium-nickel alloy, nickel chromium lump, nickel chromium powder, etc. Nichrome alloy can be defined as an alloy consisting of various alloys of nickel, chromium, and iron. Nichrome is one of the oldest forms of resistance heating alloy. Nichrome alloy generally consists of 80% nickel and 20% chromium by mass. Additionally, as per application, there are various other combinations of metals. Nichrome is silvery grey in color and has high melting point of about 1,400°celcius. Nichrome alloy has low manufacturing cost, besides strength, ductility, resistance to oxidation, and stability at high temperature. It also has good resistance power to flow the electrons. These unique properties of nichrome alloy make them suitable for applications such as hair dryers and heat guns. Nichrome alloy has high resistance power to oxidation. This property makes nichrome a suitable material for use of heating elements. Heating elements in household appliances are made of thick nichrome wire. During this process, nichrome is wound in coils to a certain electrical resistance before current is passed through to produce heat. When nichrome is heated in high temperature, it develops an outer layer of chromium oxide, unlike other metals which begin to oxidize when heated in air.
