## Abstracts

Night vision, also known as image intensification, allows humans to see in low to zero light conditions. Night vision is made possible by a combination of two approaches; sufficient spectral range, and sufficient intensity range. A device (NVD) works by collecting photons through a lens (NVIS). Then they pass through a photocathode which converts the photons into electrons. These electrons then pass through a microchannel plate, consisting of millions of closely spaced channels. In here the electrons can hit the walls so they will release thousands of additional electrons. Finally, the multiplied electrons will hit a phosphor screen where they get turned back into light. This light is thousands of times brighter than the original light and is in the visual spectrum of the human eye. The intensified light is in the same orientation as it came in providing a clear view of objects in the dark.
