Abstracts

Polyoxymethylene (POM) is a high-performance engineered thermoplastic, which is traditionally produced through ring opening polymerization of formaldehyde and is mainly supplied in the form of pellets. POM resins are produced by the process of polymerization of formaldehyde so as to provide the homopolymers and copolymers by deploying the other monomers. They are known for its several constructive and mechanical properties which makes them a suitable material to replace metal in production of several medical devices. POM is known to provide metal-like machining properties along with thermal and dimensional stability, ultra-high modulus, enhanced strength, hardness and rigidity, minimal friction coefficient and gas/vapor permeability, dielectric strength, and better retention characteristics at elevated temperature. All such properties make it an ideal material to be used in production of several medical devices and equipment such as dialysis machines, handles for instrument, pharmaceutical closure, inhalers, insulin pens and other such application areas.
