Inside the dehumidifier, the dehumidification rotor sealing system is divided into a treatment area and a regeneration area. The dehumidification rotor rotates slowly at a speed of 8-12 revolutions per hour to ensure that the entire dehumidification work is a continuous process. When the treated humid air (called treatment air) enters the 270° fan-shaped treatment area of the runner, the water molecules in the air are absorbed by the hygroscopic agent in the runner, and the water vapor undergoes a phase change at the same time, releasing latent heat; The runner tends to be saturated because it absorbs a certain amount of moisture; at this time, the processing air becomes dry and hot air due to the reduction of its own moisture and the release of latent heat; and the dry air is sent out through the processing fan. At the same time, in the regeneration area, the other air passes through the regeneration heater, becomes high temperature air (usually 100-140 °) and passes through the runner after moisture absorption, so that the absorbed water in the runner evaporates, thus restoring the rotation speed. At the same time, the regeneration air becomes moist air due to the evaporation of the moisture of the runner; after that, the moist air is discharged to the outside through the regeneration fan.
