Abstracts

Sangers sequencing service involves copying single-stranded DNA with chemically altered bases called dideoxynucleotides which when incorporated at the 3' end of the growing chain, terminate the chain selectively at A, C, G, or T. The terminated chains are then resolved by capillary electrophoresis. Sanger sequencing are primarily used to sequence individual pieces of DNA (such as DNA copied in PCR or bacterial plasmids). It gives high-quality sequence for relatively long stretches of DNA (up to 900 base pairs).
