Abstracts

Scanning laser ophthalmoscopy (SLO) is a method of examination of the eye. It uses the technique of confocal laser scanning microscopy for diagnostic imaging of the retina or cornea of the human eye. As a method used to image the retina with a high degree of spatial sensitivity, it is helpful in the diagnosis of glaucoma, macular degeneration, and other retinal disorders. It has further been combined with adaptive optics technology to provide sharper images of the retina. SLO employs lasers of different wavelengths that scan across the fundus in a raster pattern to illuminate and record reflectance or fluorescence, point-by-point at high speeds. This scanning technique lessens the need for pupillary dilation. The instrument offers several retinal imaging modalities, including monochromatic reflectance, FA, ICG angiography, and fundus autofluorescence. Although not capable of true color imaging, multiple monochrome laser images taken simultaneously can be combined to create pseudo-color images.
