## Abstracts

A chemical layer on silicon can be formed through the shared valence electrons between oxygen and silicon. These bonds allow the surface of silicon to rid itself of the dangling bonds. Mid-gap states prevent the semiconductor from reaching its desired band gap. Since the native oxide layer is chemically different from the grown silicon dioxide, it is not the same material. The two layers have different physical properties. The former has a higher refractive index, which is similar to that of silicon dioxide. The latter is about half the thickness of the original layer.
