Abstracts

Wind turbines are designed to generate electricity as cheaply as possible by utilizing wind energy. Therefore, wind turbines are generally designed so that they yield maximum output at wind speed of around 33 mph. They are designed specifically for certain wind speed. In case of stronger winds, it is necessary to waste the part of wind energy attacking on to the rotor blades, in order to prevent any significant damage to the turbine. Pitch and yaw control systems are used to prevent such damage. At high wind speed, pitch angle control or adjustments is the most effective way to control the power output. This is achieved simply by changing the aerodynamic force on the blade. When the power output becomes too high, the electronic controller immediately sends a signal to pitch control mechanism. The pitch control mechanism then pitches or turns the rotor blade slightly away from approaching direction of the wind. The pitch system also brings back the rotor to original position when the desired wind speeds are achieved.
