Abstracts

Centerless grinding is a machining process that uses abrasive cutting to remove material from a work piece. Centerless grinding differs from centered grinding operations in that no spindle or fixture is used to locate and secure the work piece; the work piece is secured between two rotary grinding wheels, and the speed of their rotation relative to each other determines the rate at which material is removed from the work piece.

Centerless grinding is typically used in preference to other grinding processes for operations where many parts must be processed in a short time.

Centerless grinding uses purpose-built centerless grinding machines. Such a machine will always include the grinding wheel, regulating wheel, and some means of supporting a work piece. Modern machines involve computer numerical control to allow automation and improve precision. Grinding wheels are interchangeable, to allow for different grits and shapes. Machines designed to accommodate through-feed grinding operations will allow the angle of the regulating wheel to be adjusted, to accommodate parts of different sizes.

In the coming years there is an increasing demand for centerless grinding machine in the regions of Japan and Europe that is expected to drive the market for more advanced centerless grinding machine. Rapid industrialization, development of urbanization and stable rise in commercial activity, particularly with automobile, electronic, aerospace, construction machinery, medical will drive growth in Asia markets.
