Abstracts

Mammography X-ray Unit is the equipment using low-energy X-rays (usually around 30 kVp) to examine the human breast, and it is used as a diagnostic and screening tool. Mammography X-ray Unit is for the early detection of breast cancer, typically through characteristic masses' detection.

Like all X-rays equipment, Mammography X-ray Unit use ionizing radiation to create images. These images are then analyzed for any abnormal findings. It is normal to use lower-energy X-rays (typically Mo-K) than those used for radiography of bones. Ultrasound, ductography, positron emission mammography (PEM), and magnetic resonance imaging (MRI) are adjuncts to mammography. Ultrasound is typically used for further evaluation of masses found on mammography or palpable masses not seen on mammograms. Ductograms are still used in some institutions for evaluation of bloody nipple discharge when the mammogram is non-diagnostic. MRI can be useful for further evaluation of questionable findings as well as for screening pre-surgical evaluation in patients with known breast cancer to detect any additional lesions that might change the surgical approach.

The industry's major producers are Hologic, GE Healthcare and Siemens, which together accounted for about 72% of revenue in 2018.
