Abstracts

A Signal Booster (also known as cellular repeater or amplifier), in the cell phone industry, is a device used for boosting the cell phone reception to the local area by the usage of a reception antenna, a signal amplifier, and an internal rebroadcast antenna. These are similar to the cellular broadcast towers used for broadcasting by the network providers, but are much smaller, usually intended for use in one building. Modern cellular repeater amplifiers can rebroadcast cellular signals inside a building. The systems usually use an external, directional antenna to collect the best cellular signal, which is then transmitted to an amplifier unit which amplifies the signal, and retransmits it locally, providing significantly improved signal strength. The more advanced models often also allow multiple cell phones to use the same repeater at the same time, so are suitable for commercial as well as home use.

Asia-Pacific is poised to grow at the highest CAGR during the forecast period owing to rising population of urban residents, increasing disposable income in this region, and rising focus of prominent players on the APAC market increasing product availability. The product average price declined in the past few years due to the technology development, the average price will keep this trend in the few future years due to increasing mature manufacturing technology and lowering cost of raw materials. Strong market competition is resulting in annual 2 percent price erosion.

The market for Signal Booster is expected to grow rapidly over the coming years, particularly in the USA. This is due to the combination of the poor network coverage in some areas, and the large scale departure from the land-line system. This combined with the low population density (compared with Europe and Japan) means that many people will have to use some method to improve their home signal
