Abstracts

High Intensity Focused Ultrasound (HIFU) is a focal therapy technique, which targets the cancer tumors with little to no damage of the non-cancerous tissue surrounding them. High-intensity focused ultrasound (HIFU) technology is maturing very rapidly around the world with diverse clinical applications. In terms of oncology, HIFU has considerable potential as it destroys the cancerous cells non-invasively. Surgery performed using high-intensity focused ultrasound (HIFU) technology in combination with modern imaging systems, has the potential to ablate cancerous cell with great precision, giving it all benefits of non-invasive surgery such as it limits the impact of treatment on patient's daily life and reduces recovery time as well.

Around the world, nearly 200 thousand patients have been treated with High-intensity focused ultrasound (HIFU) in 2017. Uterine fibroids, Prostate diseases, Breast tumors, Liver tumors are some of the major patient's indications treated using HIFU technology. It is believed that with new regulatory approvals and the development of HIFU technology will indeed drive high-intensity focused ultrasound business around the world.

Preferences of minimal invasive surgery, is also expected to boost the demand of high-intensity focused ultrasound device in the coming years. Around the world, there are more than 80 manufacturers who have been working vigorously to meet the thriving demand of HIFU devices. In the context of HIFU commercial treatment sites, there are nearly 700 sites of which around 400 HIFU commercial treatment sites are located in

Europe itself.
