Abstracts

Dialysis is the artificial process of eliminating waste and unwanted water from the blood. It is carried out by using a special fluid called dialysate, a mixture of pure water and chemicals, is carefully controlled to pull wastes out of your blood without removing substances your body needs. There are two types of dialysis: hemodialysis and peritoneal dialysis. Hemodialysis removes wastes and water by circulating blood outside the body through an external filter, called a dialyzer and in peritoneal dialysis, wastes and water are removed from the blood inside the body using the peritoneum as a natural semipermeable membrane.

End stage renal disease (ESRD) is the last stage of chronic kidney disease. This is the situation when kidney is functioning below 10% of their normal function and they can no longer support a person's day to day life. The common causes of ESRD include high blood pressure, atherosclerosis, and genetic disorders. ESRD treatment is carried out either by dialysis or kidney transplant.
